

Definitions:

- **Rational Expression:** is the quotient of two polynomials. For example,

$$\frac{x}{y}, \quad \frac{x+1}{3x-2}, \quad \frac{x^2 - 3x + 4}{x^6 - 3}$$

are all rational expressions.

- **Lowest terms:** A rational expression is in lowest terms when the numerator and denominator contain no common factors.

Important Properties:

- **To add or subtract rational expressions:** you MUST have a common denominator. Therefore, factor each denominator first to find a common denominator. Then you can add (or subtract) the terms and simplify.
- Remember that $\frac{a}{b} + \frac{c}{b} = \frac{a+c}{b}$.
- To find the common denominator, it is NOT always necessary to multiply all denominators together.
- Remember that $a - b = -(b - a)$.

Common Mistakes to Avoid:

- To add and subtract rational expressions you MUST have a common denominator. Be aware that

$$\frac{1}{a} + \frac{1}{b} \neq \frac{1}{a+b}.$$

- When subtracting rational expressions remember to distribute the subtraction sign to every term in the numerator of the fraction that follows it. For example,

$$\frac{x}{x-2} - \frac{x+1}{x-2} = \frac{x - (x+1)}{x-2} = \frac{x - x - 1}{x-2} = \frac{-1}{x-2}.$$

- $\frac{a}{b+c} \neq \frac{a}{b} + \frac{a}{c}$.
- You CANNOT obtain a common denominator by adding (or subtracting) the same constant in the numerator and denominator. Therefore,

$$\frac{a}{b} \neq \frac{a+c}{b+c}.$$

PROBLEMSPerform the indicated operations and simplify.
