

## The Keith-Leffler Model

## The Problem

- Suppose it costs \$10 to make a high quality product. Competition will force the price to \$10. Hence
  - If you can make a low quality product for \$5 and pass it off you can make money until caught.
  - But there is no reward for making a high quality product.

## Assumptions

- Two levels of quality,  $q_{high}$  and  $q_{min}$ .

## Assumptions

- Two levels of quality,  $q_{high}$  and  $q_{min}$ .
- Higher quality products cost more to produce.
- The cost function is

$$C(X, q_{high})$$

or

$$C(X, q_{min})$$

## More Assumptions

- The public cannot tell in advance whether a firm produces a high quality or a low quality product, but can after a year.

## More Assumptions

- The public cannot tell in advance whether a firm produces a high quality or a low quality product, but can after a year.
- Consumers know - don't ask how - the minimum cost of producing both  $q_{high}$  and  $q_{min}$ .
